

Comparison with published source constraints

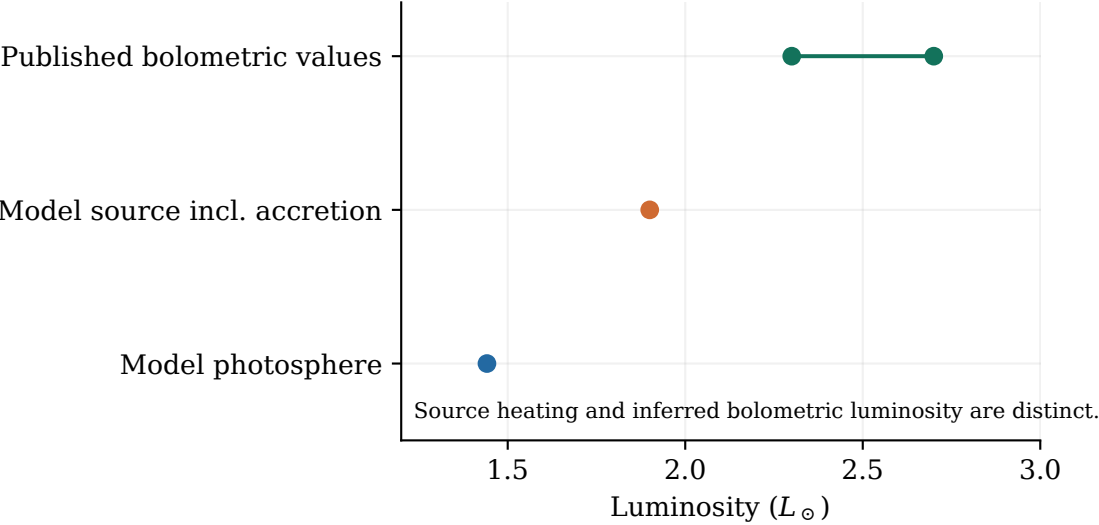

(a) Published inclination estimates

(b) Adopted source distances

(c) Luminosity definitions

(d) Scope and applicability of published constraints

- Envelope grain size:**
The $\geq 10\text{-}\mu\text{m}$ radiative-alignment argument is not a source-specific lower limit.
- Extinction:**
Jet $AV \approx 17\text{--}20$ and apparent silicate $AV \approx 33$ sample different sightlines and assumptions.
- Grain populations:**
Disk and scattering-envelope constraints probe distinct grain populations.
- Mass and cavity:**
Comparisons depend on opacity, gas/dust ratio, spatial extent and full/half-angle convention.

References and measurement definitions are provided in the text. The displayed estimates do not constitute a combined posterior.
